

Peptide Elongation Using α -NCAs Both as Nucleophiles and Electrophiles

Selected examples:

^a Reaction time of final step was 10 s (flow) + 1 min (batch). ^b Reaction time of second step was 15 s. ^c Reaction time of final step was 3 h (batch). ^d H-AA-OPG² (1.5 equiv) was used.

Significance: Peptides are one of the most useful compounds as drugs. However, conventional methods for peptide synthesis require deprotection steps and cumbersome purification. The authors have developed a rapid and column-chromatography-free three-component peptide-coupling reaction using α -amino acid *N*-carboxy anhydrides (α -NCAs) both as nucleophiles and electrophiles.

Comment: First, the nitrogen of the α -NCAs reacts with amino acid chloride as a nucleophile. Subsequently, a reaction occurs between the acid anhydride moiety of α -NCAs as an electrophile and the amino group of the amino ester, resulting in a formation of various peptides.
