“Parenthesis sign” in Eastern equine encephalitis

“A 65-year-old man from the Northeastern United States presented in the summer with headaches, fever, and severe encephalopathy. Cerebrospinal fluid (CSF) demonstrated lymphocytic pleocytosis and hyperproteinorachia. Neuroimaging is shown in Figure 1 and 2. Serum and CSF showed positive immunoglobulin M (IgM) antibodies to Eastern equine encephalitis virus (EEEV).

EEEV is a mosquito-borne alphavirus. Although rare, it can cause severe arboviral encephalitis, with mortality >33%. Magnetic resonance imaging features such as the “parenthesis sign” (Figure 1) can help distinguish between Eastern equine encephalitis and other encephalitides. Although most publications on EEEV originate from North America, EEEV and other related alphaviruses also circulate in the Caribbean, Central America, and South America.

Figure 1  T2/fluid-attenuated inversion recovery (FLAIR) axial MRI shows bilateral, relatively symmetric hyperintensities within the basal ganglia, insulae, subcortical white matter, and thalami, as well as in the inferior right frontal lobe. Marked linear hyperintensities are present in the external capsules (arrows), and parts of the internal capsules (arrowheads) bilaterally. This finding, known as the “parenthesis sign”, may help differentiate between Eastern equine encephalitis and other encephalitides.
