Introduction

The increased invasiveness of endoscopic procedures has resulted in a higher number of complications, such as bleeding or perforations. Although surgery still represents the mainstay in the management of these complications, new endoscopic devices have been developed to allow endoscopic treatment of fistulas, perforations, and post-polypectomy bleeding. The Ovesco over-the-scope clip (OTSC) system (Ovesco Endoscopy AG, Tübingen, Germany) has shown promising results in the treatment of gastrointestinal fistulas [1], iatrogenic gastrointestinal perforations [2], and bleeding [3, 4]. In addition, the Ovesco OTSC has been proposed for endoscopic full thickness resection (EFTR) of epithelial and submucosal tumors [5, 6].

More recently, the Padlock Clip™ (Aponos Medical, Kingston, NH, United States), a new OTSC device, has been introduced into clinical practice. This device is conceptually similar to the Ovesco system, but has some features which make it very attractive. Few studies have reported on the efficacy of this device in clinical practice [7–9]. Considering the emerging role of these devices in clinical practice, we decided to describe our experiences with this novel OTSC system in the treatment of gastrointestinal wall defects and EFTR.

Case series

We describe the results of the treatment of 14 consecutive patients (eight men, six women, 63–86 years) with the Padlock Clip over an 18-month period in two endoscopy units. Indications for clipping were: (i) gastrointestinal fistulas or iatrogenic perforations, (ii) gastrointestinal bleeding but non-responder to thermal and/or mechanical treatments, and (iii) EFTR of colorectal lesions with non-lifting sign. All patients provided informed consent to undergo endoscopy, and re-endoscopy was performed according to clinical follow-up.

The Padlock Clip is an 11 mm hexagonal nitinol ring with six inner prongs. The clip is released by its Lock-It™ delivery system that consists of an applicator cap, similar to the variceal band-ligation cap (Fig. 1). The applicator cap is available in two models: (1) Standard for endoscopes with a diameter of distal tip between 9.5 and 11 mm, and (2) Pro-Select™ for endoscopes with a diameter of distal tip between 11.5 and 14 mm. In the Standard model, the depth of the tissue chamber is fixed (10 mm), whereas in the Pro-Select™ model, the depth of the tissue chamber depends on the diameter of the distal tip of the scope, ranging from 8 mm for 12 mm scopes to 20 mm for 14 mm scopes. In our series, we used the Standard model for First clinical experiences with a novel endoscopic over-the-scope clip system

ABSTRACT
We describe our experience with a new over-the-scope clip (OTSC) system (Padlock Clip™) in the treatment of 14 patients. Eight of the 14 patients were treated for closure of gastrointestinal fistulas (n = 4), iatrogenic gastrointestinal perforations (n = 2), or hemostasis of post-polypectomy bleeding (n = 2). The site of clipping was the lower gastrointestinal tract in five patients and the upper gastrointestinal tract in three patients. The clip was successfully delivered in seven out of the eight patients and clinical success was achieved in all patients. Endoscopic full thickness resection (EFTR) was performed to treat six patients: four with recurrent adenoma (n = 4), one with ulcerated nodules at ileorectal anastomosis, and one with a neuroendocrine tumor of the rectum. A complete intestinal wall resection was achieved in three of the six patients (50%) and an R0 resection in five of the six patients (83.3%). No complications related to the procedure and no recurrence at endoscopic follow-up were observed in any patient. The novel Padlock Clip seems to be an effective and safe tool to treat gastrointestinal fistulas, perforations or post-polypectomy bleeding, and to perform EFTR.
gastroscopes and the Pro-Select™ model for standard colonoscopes.

The clip is preassembled in an opened position on the delivery system and it is released by a trigger cable running parallel to the scope that is connected to a handle (▶ Video 1). After suction of tissue into the cap to obtain adhesion to the instrument tip, the clip is released by pressing the handle which pushes the wire within the cable. When deployed, the shape-memory effect and the high elasticity of nitinol cause the closure of the clip. Its six inner prongs penetrate and pull the tissue inward resulting in a pseudo-polyp of closed tissue (▶ Fig. 2 and ▶ Video 2). When performing EFTR, the entrapped tissue is resected with an oval snare above the closed clip by applying cutting current (▶ Fig. 3 and ▶ Video 3). Patients undergoing EFTR have been hospitalized for one night and then discharged the day after if asymptomatic. Technical success was defined as closure of the clip and the successful resection of the trapped tissue; specimens were classified as: “deep muscle resection” (DMR) when a deep muscle margin was present at the vertical margin; “full thickness resection” (FTR) if complete intestinal wall was included; R1 resection if neoplastic tissue was still evident at the lateral margins, and R0 resection if no neoplastic remnant was evident.

The characteristics of the eight patients with fistulas, perforations, or post-polypectomy bleeding are summarized in ▶ Table 1. Indications for clipping were closure of gastrointestinal fistulas (n = 4), management of iatrogenic gastrointestinal perforations (n = 2), or hemostasis of post-polypectomy bleeding (n = 2). Three clips were applied in the upper gastrointestinal tract (stomach and duodenum) and five clips in the lower gastrointestinal tract (rectum and sigmoid colon). In one patient, the delivery system failed to release the clip into the duodenum and the wall defect was closed with two through-the-scope (TTS) clips. Clinical success (healing of defect or resolution of bleeding) was achieved in all patients. In three patients, clinical follow-up required re-endoscopy and no clip retention.
was found. No related adverse events were observed in any of the eight patients.

In ▶ Table 2, we report the features of the six patients who underwent EFTR. In four of the six patients, the indication was a recurrent adenoma after endoscopic mucosal resection (EMR, one in the rectum, one in the sigmoid colon, and one in the ascending colon) or transanal endoscopic microsurgery (TEM, one patient); in one patient, two ulcerated nodules were removed using two clips at ileorectal anastomosis in a patient operated for colon cancer; and in the last case, a depressed scar in the rectum was removed; it had resulted from previous forceps resection of a small infiltrating neuro-endocrine tumor. Technical success was recorded in all six patients. In five patients, we obtained an R0 resection as defined by histology. In the case of anastomotic recurrence of adenocarcinoma, an R1 resection was obtained, but no recurrence was seen at 6-month follow-up endoscopy. Histology demonstrated a DMR resection in three patients and a FTR in the remaining three. The mean diameter of the resected lesions was 12.5 mm (range 10–16 mm). No complications were recorded. Follow-up ranged from 3 to 15 months and no recurrence was demonstrated either macroscopically or microscopically when the scars were biopsied. No clips were found at the first endoscopic control performed after 3 months.

Discussion
The novel Padlock Clip is conceptually similar to the Ovesco clip system, but Padlock’s atypical design is likely to offer some advantages. In particular, the six inner prongs of the Padlock system, which are placed in a circumferential fashion, create a firm hold of the tissue which is easily lifted within the cap without the need for further devices such as forceps or graspers. Moreover, the system allows a thorough closure as demonstrated by an ex vivo study in explanted porcine stomachs where gas inflation revealed a mean leak pressure of 68 mmHg [10].

In eight out of 14 patients, the Padlock was used to manage wall defects and post-polypectomy intraprocedural bleeding. Successful OTSC deployment was achieved in all but one patient, a patient with an iatrogenic perforation of the duodenum that was then successfully closed with two through-the-scope...

clips. Technical failure of clip release was probably due to the angulated position of the target site. In the other seven patients, the Padlock clipping resulted in long-term clinical success, with definitive closure of the gastrointestinal defects and resolution of intraprocedural bleeding. Interestingly, in our series, the Padlock clip was used successfully to treat two gastrointestinal fistulas after the application of an Ovesco clip. Although no comparison studies between the two systems are available, Padlock seems to be a reliable option in the management of gastrointestinal fistulas.

We describe for the first time the use of the Padlock system to perform EFTR in six patients, obtaining a FTR in 50% of patients attempted and at least a DMR in the remaining 50%. We were able to achieve an R0 resection in five out of the six (83.3%) patients without any complications. In the single case in which resection was considered incomplete, surgery was not indicated. Although we could not exclude the presence of residual tumoral cells buried within the closure of the clip, no local recurrence was revealed by endoscopy with random biopsies at 6-month follow-up.

Fahndrich and Sandmann [5] performed 17 EFTR (14 in the colon) without any complications using the standard Ovesco clip, and achieved a complete resection in 70% of patients, an FTR in 64% and an R0 resection in 100%. Schmidt et al. [6] used the dedicated Ovesco device for EFTR to perform resection in 25 patients (to diagnose Hirschsprung’s disease in one patient). In one patient, the progression of the scope was hindered by a diverticular stricture of the sigmoid colon; in 20 out of 24 patients, the EFTR was successful, with histologically proven FTR in 21 patients and R0 resection in 18 patients. Two burning syndromes and one minor bleeding were reported. In all these patients, a grasping device was used to pull the tissue into the cap. In our application of the Padlock Clip, we did not use any grasping forceps (although it is theoretically possible). In addition, the diameter of the Padlock Clip and the length of the cap are smaller than in the dedicated Ovesco device for EFTR. These differences explain the smaller size of the specimens compared to the size of the specimens in the Schmidt study [6]. A combination of grasping and aspiration needs to be tested in a larger series and clinical trials to improve the outcomes of Padlock Clip-assisted EFTR.

The main limitations of our study were the small number of patients and the nature of the study (non-controlled design, variable indications). Despite these limitations, the new Padlock system seems to be an effective and safe tool, even when it is used to perform EFTR. However, further prospective clinical studies are needed to confirm its efficacy and safety, as well as to evaluate its correct use in clinical practice and explore new clinical indications.
