Abstract: A new chiral dipyridylphosphine ligand Tol-P-Phos has been synthesized and the structure of the complex of (R)-Tol-P-Phos oxide with (–)-dibenzoyl-L-tartaric acid [(–)-DBT] was determined by single crystal X-ray diffraction. The ruthenium complex of Tol-P-Phos, Ru(R-Tol-P-Phos)(C6H6)Cl2, has been found to be a highly active and enantioselective catalyst in the asymmetric hydrogenation of β-ketoesters (up to 98.2% e.e.). The catalyst is also found to be air-stable even in solution.

Key words: asymmetric catalysis, hydrogenation, dipyridylphosphine ligands, ruthenium complex, β-ketoester

The search for new chiral ligands is an ongoing process in the field of asymmetric synthesis. Although more than a thousand chiral nonracemic diphosphines have been synthesized and the efficiency of catalysts derived from these ligands have been established, the possibility of discovering catalysts with improved utility, activity, and selectivity by designing new ligands remains to be an area of active research.

Over the past two decades, tremendous success has been achieved in the use of chiral arylphosphine ligands such as BINAP, BIPHEP, MeO-BIPHEP, and DuPhos, etc. in Rh- or Ru-catalyzed asymmetric hydrogenation reactions. As an effort to expand the scope of the arylphosphine ligands and their application in homogeneous catalysis, transition-metal complexes containing pyridylphosphine ligands have been synthesized and tested in homogeneous catalysis. Unfortunately, the tested complexes were found to be inactive in the homogeneous hydrogenations owing to the pyridyl group which coordinated to the metal center and rendered the complex coordinately saturated. By preventing the coordination of the pyridyl groups via the use of bulky substituents, we found that the resulting rhodium(I) complex was effective for the hydrogenation of aldehydes, olefins, and imines.

Scheme Synthesis of Tol-P-Phos

Synlett 2001, SI, 1050–1054  ISSN 0936-5214 © Thieme Stuttgart · New York
Inspired by the success of the modified pyridylphosphine ligand, we have developed a chiral dipyridylphosphine ligand \(2,2',6,6'\text{-} \text{tetramethoxy}\text{-}4,4'\text{-} \text{bis(diphenylphosphino)}\text{-}3,3'\text{-} \text{bipyrindine (P-Phos)},\) which was found to be very effective in the Ru catalyzed asymmetric hydrogenation of 2-(6'-methoxy-2'-naphthyl)propeneoic acid to give the nonsteroidal anti-inflammatory drug naproxen.\(^6,7\) In this paper, we report the synthesis, characterization and application of a new dipyridylphosphine ligand, \(2,2',6,6'\text{-} \text{tetramethoxy}\text{-}4,4'\text{-} \text{bis[di(}4\text{-} \text{tolyl)}\text{phosphino)}\text{-}3,3'\text{-} \text{bipyrindine (Tol-P-Phos)},\)

The synthetic route of Tol-P-Phos is outlined in the Scheme. The slow addition of bromine to commercially available \(\text{C}_6\text{H}_6\) between \(-30 \text{ } ^\circ\text{C} \text{ to } -40\text{ } ^\circ\text{C} \) gave 3-bromo-2,6-dimethoxypyrididine (2) in 76% yield.\(^8\) The regioselective lithiation\(^9\) of 2 with lithium diisopropylamide (LDA) in THF at \(-78\text{ } ^\circ\text{C}\), followed by the addition of di(4-methylphenyl)phosphine chloride (3) provided 3-bromo-2,6- \text{dimethoxy-4-di(}\text{p}-\text{methylphenyl)}\text{phosphinopyridine (4), 55% yield}, while 3 was prepared according to the literature method in 73% yield.\(^10\) Oxidation of 4 with hydrogen peroxide in acetone at 0\text{ } ^\circ\text{C} produced 5 in 99% yield. The racemic dipyridylphosphine oxide 6 was obtained via Ullmann coupling\(^11\) of 5.

The resolution of racemate \((\pm)\text{-}6\) was achieved by the use of enantiomers of DBT.\(^12\) When a solution of \((2R,3R)-(\text{--})-\text{DBT}\) in ethyl acetate was added to a boiling solution of racemic compound 6 in chloroform, a 1:1 complex of \((+)\text{-}6\) and \((\text{--})\text{-DBT} \[(+)\text{-}6-(\text{--})\text{-DBT}\] precipitated as a crystalline solid. X-ray structure analysis (Figure) revealed that the crystals are built up of infinite close-packed chains in which equimolar \((+)\text{-}6\) and \((\text{--})\text{-DBT}\) are connected in a regularly alternating way through two inter-molecular hydrogen bonds between oxygen atoms \([\text{O}(1)\text{ and O}(2)]\) of the P=O groups in compound 6 and hydrogen atoms of the COOH groups of DBT.

The low solubility of complex \((+)\text{-}6-(\text{--})\text{-DBT}\) is attributable to such a linear polymeric structure. From the internal comparison with \((2R,3R)-(\text{--})\text{-DBT}\), the absolute configuration of \((+)\text{-}6\) was determined to be \(R\). Subsequent decomposition of complex \((+)\text{-}6-(\text{--})\text{-DBT}\) with aq. NaOH provided enantiomerically pure \((R)-(+)\text{-}6\) in 91% yield based on the \((\pm)\text{-}6\) used. \((S)-(\text{--})\text{-}6\) was recovered from the mother liquor of the recrystallization by treatment with aq. NaOH. This crude product could be further purified via the formation of the complex with \((+)\text{-DBT}\). Thus, both \((R)-(+)\text{-}6\) and \((S)-(\text{--})\text{-}6\) enantiomers were effectively obtained by choosing the handedness of the resolving agents. Reduction of enantiomerically pure 6 with trichlorosilane in the presence of triethylamine led to the targeted enantiomers of atropisomeric ligands 7 (92% yield), the structure of which was confirmed by \(1\text{H}, 13\text{C}, 31\text{P}\) NMR, and elemental analysis.

Using Mashima et al’s method,\(^13\) Ru(\(R\text{-Tol-P-Phos)(C}_6\text{H}_6\text{Cl}_2\)) 8 was prepared by mixing \([\text{RuCl}_2(\text{C}_6\text{H}_6)]\) with \(R\text{-Tol-P-Phos}\) in an \(8:1\) mixture of ethanol-benzene and the complex was isolated as a reddish brown solid. The structure of the complex was characterized by \(1\text{H}, \text{and } 31\text{P}\) NMR.\(^14\)
was found to be a highly effective catalyst for the asymmetric hydrogenation of \( \beta \)-ketoesters (Table 1). The reactions proceeded smoothly at 80-90 °C and under 300 psi of \( \text{H}_2 \) in two hours and the ee value is up to 98.2% (entry 1).

The hydrogenation of \( 9c \) leads to a useful pharmaceutical intermediate, \((S)-3\)-hydroxy- \( 3 \)-phenyl propionate (10c). Table 2 indicates that the rate and enantioselectivity of this reaction were influenced by the choice of solvent, \( \text{H}_2 \) pressure and the molar ratio of substrate to catalyst (S/C). The mixed solvent of EtOH–\( \text{CH}_2 \text{Cl}_2 \) (1:1) and lower \( \text{H}_2 \) pressure are favorable for higher enatioselectivity. Entry 11-13 were carried out in a larger scale (30 g substrate) and the results indicated that no substantial decrease of ee (95.9% ee, entry 11) with high S/C ratio. Although enantioselectivity is a major concern in modern asymmetric synthesis, the reactivity and productivity are also important factors of consideration in determining the commercial feasibility of a reaction. Thus the demonstration of carrying out the reaction at high S/C ratio without losing enantioselectivity was encouraging. Other desirable features of a good catalyst system include the ease of catalyst preparation and handling as well as the operational simplicity of the experimental procedures. A usual problem associated with the use of noble metal phosphine catalysts is the air-sensitivity of the catalysts. The oxidation of the active catalyst by trace amounts of oxygen in the reaction system often makes irreproducible results in many reactions. This problem is even more severe in industrial applications in which the rigorous de-gassing is usually more difficult than the laboratory-scale operations. Therefore, it is highly desirable to develop effective catalysts with good air-stability. In this study we were delighted to find that the Ru(\( R \)-Tol-P-Phos)(\( C_6 \text{H}_6 \))\( \text{Cl}_2 \) catalyst system to be highly air-stable. In a simple stability test we found that when the substrate (\( 9c \)) and the Ru(\( R \)-Tol-P-Phos) catalyst were added to the stainless steel autoclave in air and when the solvents were not degassed and dried prior to use, the activity and enatioselectivity of the catalyst (8) remained to be unchanged (96.4% ee, entry 14) from the air-proved system (96.2% ee, entry 8). Further investigation showed that the activity and enatioselectivity of 8 remained to be the same even its solution in EtOH and \( \text{CH}_2 \text{Cl}_2 \) were stirred for 10 hours under air prior to its application (95.7% ee, entry 15). These results compared favorably with those obtained from the use of Ru(\( R \)-Bi-nap)(\( C_6 \text{H}_6 \))\( \text{Cl}_2 \) as catalyst precursor in a side by side comparison study.

The air-stability of 8 was also supported by a \( ^{31} \text{P} \) NMR study (Figure 2). After the catalyst solution was exposed to air for 10 h, its \( ^{31} \text{P} \) NMR spectrum showed no variation in comparison with that determined under \( \text{N}_2 \) [\( \text{CDCl}_3 \), 500 MHz, \( \delta \) 31.15 (d, \( J = 62.7 \) Hz), 38.28 (d, \( J = 62.71 \) Hz)]. These results showed excellent potential for the practical applications of the P-Phos type ligands in asymmetric catalytic reactions.

In conclusion, we have developed a new dipyridylphosphine ligand and its Ru complex 8 has been found to be a highly effective catalyst in the asymmetric hydrogenation of \( \beta \)-ketoesters. It is of high interest to note that 8 is stable to air, which makes the experiments convenient to operate and also shows a good potential for its industrial application.
