Peribiliary Cysts 
Both in the Cystic Duct and in the Intrahepatic Biliary Tract

Figure 1  A 72-year-old man complained of low-grade fever and right upper quadrant abdominal pain. Endoscopic retrograde cholangiopancreatography revealed radiolucent areas in the extrahepatic bile duct (white arrows) and in the cystic duct (large white arrow), suggestive of a gallstone. Cholecystectomy and choledocholithotomy were carried out.

Figure 3  Magnetic resonance cholangiopancreatography undertaken after surgery demonstrates numerous cysts along the intrahepatic bile ducts in a single image.

Figure 2  a On the resected specimen, a smooth-surfaced intramural cyst (black arrow) was identified in the cystic duct, in addition to gallstones in the common bile duct and the gallbladder. b, c Photomicrographs show that the cyst is lined with a layer of columnar epithelium, and mildly periductal glands are seen in the cyst wall (hematoxylin and eosin; magnification × 13 (b) and × 135 (c).

Figure 4  T-tube cholangioscopy reveals an elevated lesion covered with normal mucosa in the intrahepatic bile duct.
