Cerium(III) Chloride Heptahydrate: CeCl₃⋅7H₂O

Compiled by Ravula Satheesh Babu

Ravula Satheesh Babu was born on 22nd March 1971 at Warangal (India). He studied his Bachelor of Science at Kakatiya University, his Bachelor of Education Andhra University, and Master of Science at the Department of Chemistry, University of Pune. He has submitted his PhD thesis on 'Stereoselective Total Synthesis of Artemisinin and Development of Novel Synthetic Methodologies' under the guidance of Prof. J. S. Yadav, FNA at IICT, Hyderabad. Presently he is working as ‘Postdoctoral Research Associate’ at West Virginia University with Prof. George A. O’Doherty.

Introduction
Few areas of synthetic chemistry have witnessed a growth as explosive as that brought about by the application of lanthanide reagents to organic synthesis. Cerium(III) chloride heptahydrate¹ is a commercially available lanthanide reagent which is water tolerant, non-toxic, easy to handle, inexpensive and can be used without further purification.

Abstracts
A) Luche² introduced this reagent in 1978 for the selective 1,2 reduction of enones. Since the preparation of organocerium compounds by Imamoto and co-workers³ in early 1980's these are now widely applied as the reagent of choice to facilitate nucleophilic addition reactions. Recently, Bartoli and co-workers⁴ demonstrated the reactivity of CeCl₃⋅7H₂O in combination with NaI for several organic transformations.

B) Luche² used the combination of CeCl₃ and NaBH₄ for selective reduction of conjugated aldehydes and ketones to allylic alcohols. This procedure has general utility and has been embraced by the synthetic organic chemistry community for 1,2 reduction of enones where other reagents (eg. DIBAL-H, LiAlH₄, Zn(BH₄)₂ or NaBH₄ alone) failed to provide the described products or gave inferior results. Similarly, selective reduction of ketones in the presence of aldehydes⁵ and selective ketalization of aldehydes in the presence of ketones⁶ were also very effective using CeCl₃. In another report, reduction of conjugated cyclohexenones was achieved using NaBH₄–CeCl₃⋅7H₂O in aliphatic alcohols.⁷

C) Cerium(III) chloride was shown to catalyze the Michael addition⁸ of 1,3 dicarbonyl compounds to α,β-unsaturated ketones and α,β-unsaturated aldehydes in the presence of NaI. The catalyst system can be easily separated from the reaction mixture and it can be reused without an appreciable loss of activity. The reactions can also be performed without solvents under microwave irradiation.⁸

D) Highly regioselective ring opening of epoxides and aziridines has been carried out using cerium(III) chloride to synthesize the corresponding chlorohydrins,11 iodohydrins,11 1,2-azidoalcohols,12 1,2-aminooalohol,11 chloramines,11 iodoamines11 and 1,2-azidoamines.11

E) Cerium(III) chloride has been used as a mild Lewis acid, and efficient catalyst for the deprotection of alcohol protecting groups such as MEM,14 Tr,15 TBDMS,16 allyl,17 prenyl,18 Me18 and PMB.19 A simple and efficient method for the conversion of alcohols into alkyl iodides20 using CeCl3 –SnCl2, providing [3+4] cycloadducts via the oxyallyl cation intermediate.21

F) α,β-Dibromo ketones react with 1,3-dienes in the presence of CeCl3 –SnCl2, providing [3+4] cycloadducts via the oxyallyl cation intermediate.21

G) Organocerium reagents22 are generated in situ by transmetalation reactions from organolithium23 or organonamagnesium reagents.4 Organocerium reagents are highly oxophilic and significantly less basic than their RLi and RMgBr counterparts.
