An 80-year-old man with persistent anemia was suspected to have a hemorrhagic lesion in the small intestine and he underwent investigation by capsule endoscopy. This examination revealed several erosions and reddened lesions in the pelvic small intestine (Figure 1). On 17 May 2005 he was started on a prostaglandin inducer, rebamipide, at a daily dose of 300 mg, and although the iron preparation he was on was stopped, there was no decrease in his hemoglobin level. On 1 July a second capsule endoscopy examination revealed marked improvement—the erosions and reddened lesions in the small intestine had resolved (Figure 2).

The second capsule endoscopy allowed observation nearly as far as the terminal ileum, where a protruding lesion was detected (Figure 3). Double-balloon endoscopy revealed a red type I polyp, about 30 cm proximal to the ileocecal valve (Figure 4). In addition, there was an advanced cancer resembling a type IIc early cancer in the ascending colon (Figure 5).

On 29 August 2005 the patient underwent surgery. The lesion in the large bowel was diagnosed as a moderately differentiated adenocarcinoma (ss, ly1, v1, n0).
and the lesion in the ileum as a well-differentiated adenocarcinoma with a component of tubular adenoma (sm1, ly0, v0). There was also a type Iic early cancer in the stomach and this lesion was resected endoscopically. The entire clinical course is summarized in Figure 6. It was not possible to determine whether this patient’s anemia had been caused by the small-intestinal lesions or by the advanced large-bowel cancer. Rebamipide, a mucoprotective agent, might be effective for the management of patients with erosions or reddened lesions in the small intestine [1–3].

Capsule endoscopy proved useful for the diagnosis of the small-intestinal lesions in this patient, but we should be aware that this method cannot provide a diagnosis of lesions that the capsule cannot reach and that it can miss small lesions in stomach.
