A clinically significant right renal mass identified as an incidental finding on endoscopic ultrasound examination

The incidence of detection of an asymptomatic malignant disease or of another clinically important condition by endoscopic ultrasound (EUS) performed for another indication is unknown and is probably much higher than is generally recognized. Renal incidentalomas identified at EUS, particularly of the right kidney, remain poorly characterized.

A 57-year-old woman with a history of acute pancreatitis presented for further evaluation by EUS. Radial EUS revealed a normal gallbladder, bile duct, pancreatic parenchyma, and pancreatic duct, and there was no evidence of regional adenopathy. An incidental lesion on the apex of the right kidney and several small renal cysts were identified, however (Fig. 1, Video 1). A linear echo endoscope examination confirmed the findings (Fig. 2), although fine-needle aspiration was not performed. These EUS findings were confirmed by a subsequent renal ultrasound examination, which revealed a 1.5-cm, echo-poor, solid-looking mass, also visualized on computed tomographic urography (Fig. 3). The patient had no history of flank discomfort, hematuria, urinary tract infection, or kidney stones. An open partial right nephrectomy was performed, when a well-circumscribed, 2-cm lesion was enucleated without complications. Histologically, this was a grade 2 T1a clear cell renal cell carcinoma, without evidence of tumor necrosis.

The widespread use of advanced imaging techniques has led to increased identification of incidental renal cell carcinomas. Solid renal masses are present in 0.32% of the population [1]. The pre-test probability of finding clinically relevant extracolonic disease in average-risk, asymptomatic adults at computed tomographic colonoscopy is reported to be 4%–86% [2]. EUS-guided fine-needle aspiration diag-
agnosis of primary renal cell carcinoma and of metastatic renal cell carcinoma to the mediastinum and pancreas has been reported [3 - 5]. This case illustrates a clinically significant finding in an area not commonly visualized by EUS.
