Diffuse cavernous hemangioma of rectosigmoid colon treated with \( n \)-butyl-2-cyanoacrylate injections

**Case 1.** A 30-year-old man was admitted to the hospital because of recurrent gastrointestinal bleedings, treated for 9 years with blood transfusions. Nine years previously his right leg was amputated because of vascular malformations. Colonoscopy revealed vascular malformations around the whole circumference of the rectum (Fig. 1, 2). Low anterior resection with mucosectomy and coloanal sleeve anastomosis did not seem feasible [5]. Thirteen procedures of endoscopic obliteration with \( n \)-butyl-2-cyanoacrylate-
late were undertaken. Histoacryl 0.5 ml diluted with lipiodol 0.7 ml was injected into vascular malformations at aliquots of 1.0 ml per injection, and up to 12 ml at each procedure. The mass of angiomatous vessels and the frequency of bleedings decreased and the patient left the hospital.

Case 2. A 26-year-old woman was admitted to our hospital because of recurrent gastrointestinal bleedings. She had a history of numerous hospitalizations and blood transfusions during the preceding 12 years. She had extensive vascular malformations over the left buttock, knee, vulva, and toes, and could not walk. Computed tomography showed a huge mass of pelvic vascular malformation (Fig. 3). Laparotomy and histology revealed cavernous hemangima (Fig. 4). Colonoscopy showed vascular malformations extending from the anal sphincter, around the whole circumference of the rectum, and, less extensive, in the sigmoid colon (Fig. 5, 6). Fifteen procedures similar to those in case 1 were completed. The patient left the hospital; unfortunately she died 4 months later due to recurrent bleeding.

Endoscopic obliteration of cavernous hemangiomas of the rectosigmoid with n-butyl-2-cyanoacrylate is an effective mode of treatment for this disease and is useful in patients who are not eligible for surgery.
