Seronegative spondyloarthropathy imaging: Looking at the past, hitting the future

Sir,
Further to the paper by Prakash et al. entitled “Seronegative spondyloarthropathy-related sacroilitis: CT, MRI features and differentials,” published in the 2014 September issue of the *Indian Journal of Radiology and Imaging*, we congratulate the authors and wish to make further comments.

The authors report the different CT and MRI features of seronegative spondylarthropathy, and state that conventional radiography is not a useful tool for early disease detection. We do agree that MR is the sole imaging modality permitting to depict bone marrow edema at the first stage of the disease before erosions and sclerosis appear. This belongs to the well-known and major ASAS criteria.[1] However, looking at the past, we assume that conventional radiology still has a place at the early-stage diagnosis. As a matter of fact, digital tomosynthesis is a low-radiation dose imaging means, a numerical revival of “conventional” tomography, which is available on a conventional remote-controlled radiology table. The extensive number of acquisition slices prevents from superimposition of anatomical structures, thus improving detection of tiny lesions such as bone erosions [Figure 1]. Tomosynthesis may, therefore, definitely help in selecting patients requiring MRI examination of the sacroiliac joint to depict subchondral edema according to the ASAS criteria.[2]

Looking at the future, PET scan may become a core diagnosis tool too. Although “standard” 18F-fluorodeoxyglucose [(18F) FDG] tracer may target and image inflammation such as the bone marrow edema areas, [18F] fluoride tracer may highlight osteoblastic activity and bone remodeling in the areas of interest [Figure 2].[3] As bone remodeling is the key point of the “functional imaging” physiopathological process of inflammation that leads to joint ankylosis, [18F] fluoride may better predict the patient’s prognosis than the other “morphological” imaging modalities, which do not reflect this dynamic process.

In conclusion, we believe that management of patient with...
Letters to the Editor

Figure 2 (A-E): Young male patient suspected of sacroiliitis undergoing PET studies (A and B) by using (18F) D-glucose and (18F) fluoride radionuclides (C and D) and MRI (STIR) (E) MRI shows no bone edema and (18F) FDG-PET shows no uptake, while (18F) fluoride-PET scan examination shows hot spot corresponding to osteoblastic bone remodeling. BioMed Central, Fischer DR, et al.

seronegative spondyloarthropathy may be improved by adding both the digital tomosynthesis (leading to prompt early-stage MRI diagnosis) and the positron emission tomography (PET) [18F] fluoride scan (prognostic tool) to the traditional MRI and CT scan imaging means.

Caveat emptor

Dear Sir,

"Caveat Emptor" is a Latin phrase for "let the buyer beware." It places on the consumers the burden to be vigilant before purchasing an item or availing themselves of a service. On a parallel track is the role of an author as a consumer when he pays for the publishing services to Open Access Journals (OAJ). Hence, it is crucial for the authors to examine the appropriateness of a journal and avoid becoming a victim.

Getting the articles published these days has become a child’s play or perhaps even easier. The perfect milieu
