ABSTRACT

Ependymomas are mostly infratentorial, intraventricular tumor, accounting for 2–9% of all central nervous system tumors. Supratentorial pure cortical ependymoma are extremely rare tumor with definite ependymal morphology and uncertain histogenesis. They are mostly low grade tumor and are cured with resection, rendering them favorable prognosis. Our case is of a 14-year-old female presenting with headache and convulsion of short duration. She underwent gross total excision of the tumor without radiation therapy and her follow-up is uneventful.

Key words: Cortical, ependymoma, extraventricular, supratentorial

Introduction

Supratentorial cortical ependymomas (CE) are unique tumor with very few cases reported so far in the literature. They occur in the superficial cortical ribbon and have no connection with the ventricular lining. These tumor have relatively benign course and shows close relationship with the recently described entity - angiocentricglioma (AG).

Case Report

A 14-year-old female came with complaint of headache, vomiting and seizure since 1-month. Her systemic examination was normal. Routine laboratory examinations were normal. Computed tomography (CT) showed a large, well-defined, extra axial right frontal mass measuring 4 cm × 3 cm × 2.6 cm associated with perifocal edema [Figure 1]. Magnetic resonance imaging (MRI) revealed 4 cm × 3 cm × 2.6 cm, right frontal mass showing contrast enhancement [Figure 2]. Radiologically the differential diagnoses given were? Meningioma and? Oligodendroglioma. Cerebrospinal fluid (CSF) examination did not reveal any atypical cells. Surgical resection of the mass was planned, and the patient underwent total resection of the tumor, which was located in the parenchyma with no dural attachment. The tumor was clearly demarcated and dissected subpially from the surrounding brain parenchyma. The surgical findings suggested no relationship with the lateral ventricular system. Intraoperative squash cytology reveal [Figure 3] cellular smear showing tumor cells arranged in papillary pattern. The individual cells are round to oval nuclei with focally prominent nucleoli and moderate amount of eosinophilic cytoplasm. At places rosette like structures were also seen favoring the diagnosis of ependymoma. Histolopathological examination of the tumor demonstrated diffuse sheet of ependymal cells with focal area showing perivascular pseudorosettes and true rosettes [Figures 4 and 5]. Immunohistochemistry reveal diffuse positive reactivity for glial fibrillary acidic protein [Figure 6] and dot like positivity for epithelial membrane antigen (EMA) [Figure 7]. The Ki-67 index was 5% [Figure 8]. These findings confirmed ependymoma, World Health Organization (WHO) Grade II. The patient’s postoperative course was uneventful. He reported no complaints at his 6-month follow-up, and CT and MRI revealed no recurrence.

Discussion

Ependymomas are central nervous system (CNS) tumor arising from ependymal cells lying on the inner surface of brain ventricle and along the central spinal cord. They are commonly seen in the cervico thoracic segment of the spinal central canal and fourth ventricle. Supratentorial cortical ependymoma is a rare entity where the tumor is seen in cortical region without any connection to the ventricular lining. The current WHO classification of CNS tumor divide ependymoma into low grade (Grade II) and high grade (Grade III) or anaplastic ependymoma, reserving
