Sir,

Focal intracranial infections remain a major source of morbidity and are often life-threatening conditions. Rapid recognition and early neurosurgical intervention combined with appropriate antimicrobial treatment give the best chances of a favorable prognosis.\textsuperscript{1} We describe a rare case of a subdural empyema (SDE) and adjacent cerebral abscess from \textit{Achromobacter} species in a young patient with hematologic malignancy.

A 39-year-old Caucasian female with multiple myeloma, was admitted in the emergencies with fever, headache, vomiting, gait disturbance, and seizures for 4 days. Neurological examination revealed a left hemiparesis, nuchal rigidity, and positive Babinski sign. Pre- and post-contrast computed tomography and magnetic resonance imaging brain scans were suggestive of right frontal SDE and adjacent early capsule formation brain abscess with perifocal edema [Figure 1a-d].

The patient underwent right frontal craniectomy and complete removal of SDE and cerebral abscess [Figure 2]. \textit{Achromobacter xylosoxidans} colonies were identified from blood samples and intracranial pus cultured on MacConkey agar. The patient received a combination of Piperacillin–Tazobactam and trimethoprim/sulfamethoxazole (TMP/SMX) intravenously for 6 weeks and she gradually recovered. She was also given oral TMP/SMX for a further 2 months, and at the time of writing this study, she is still well 1½ years after completion of therapy [Figure 3].

\textit{Achromobacter} species is often isolated from aqueous environments but is rarely recognized as a human pathogen. However, it can cause serious infections in immunosuppressed patients. \textit{Achromobacter} infections in patients with cancer, and especially in those who have underlying hematologic malignancies, usually are seen as uncomplicated hematogenous infections and are seldom accompanied by a secondary suppurative focus of infection.\textsuperscript{2,3} Isolation of \textit{Achromobacter xylosoxidans} from intracranial space was an unusual finding and to the

Figure 1: (a) Brain computed tomography scan without contrast, and (b) T1 – weighted postcontrast image reveals a hyperdense to cerebrospinal fluid right frontal subdural collection with clear capsule formation, and an adjacent intraparenchymal lesion of low signal with considerable edema. (c) Fluid-attenuated inversion recovery postcontrast sequence demonstrates a densely enhancing extraaxial lesion and a well-defined ring enhancing brain lesion. (d) On diffusion-weighted image, the core of the subdural and brain lesion has typically markedly hyperintense signal (restricted diffusion)

Figure 2: Purulent material into the subdural space after opening of the dura mater and the subdural empyema capsule
best of our knowledge is the first case that *Achromobacter xylosoxidans* implicated for an intracranial abscess formation in an adult patient who had not undergone any prior neurosurgical procedure.

**Declaration of patient consent**

The authors certify that they have obtained all appropriate patient consent forms. In the form the patient(s) has/have given his/her/their consent for his/her/their images and other clinical information to be reported in the journal. The patients understand that their names and initials will not be published and due efforts will be made to conceal their identity, but anonymity cannot be guaranteed.
