

Primary B-cell Lymphoblastic Lymphoma of the Ovary

Sir,

An 18-year-old unmarried girl presented with a 1-month history of lower abdominal pain without fever, loss of weight or appetite, or menstrual irregularity. At a local hospital, computerised tomography imaging showed a large left adnexal mass measuring 10.6 cm × 7.1 cm × 8.2 cm, for which she underwent laparotomy and ovariectomy and came to us for further management. On evaluation, she had an Eastern Cooperative Oncology Group (ECOG) performance status of one with unremarkable general physical and abdominal examination. The ovariectomy specimen reviewed at our center showed high-grade non-Hodgkin's lymphoma (NHL) confirmed as B-lymphoblastic lymphoma by immunohistochemistry [Figures 1-5]. The malignant cells were positive for LCA, CD20, C79a, CD10, and TdT and negative for staining with LMO, EMA, CD3, and CD68. The Ki-67 was strongly expressed in over 90% of the cells [Figures 1-5]. Serum alpha-fetoprotein (2.09 ng/ml), beta-human chorionic gonadotropin (2.39 mIU/ml), and lactate dehydrogenase levels (381 U/L) were normal. Her baseline hemogram and peripheral smear were normal, and there was no evidence of tumor lysis. Imaging at our center showed no residual tumor in the abdomen. Bone marrow aspiration, bone marrow trephine biopsy, and cerebrospinal fluid analysis were negative for disease

involvement. She started systemic therapy as per the Berlin Frankfurt Munster-95 acute lymphoblastic leukemia protocol and remains disease free 2 years after diagnosis.

Ovarian involvement by NHL is rare but is reported to occur either primarily or secondarily.^[1,2] Primary ovarian lymphoma (POL) accounts for 1.5% of all ovarian cancers and 0.5% of all NHLs.^[2,3] The pathogenesis is poorly understood, but the tumor may arise from B- and T-lymphocytes which are found in the ovarian cortex, follicles, or stroma.^[4] As per the criteria proposed by Fox *et al.*, ovarian lymphoma is considered to be primary when the tumor burden is confined to the ovary with or without direct lymph nodal infiltration in the adjacent region.^[5] Based on this, we diagnosed our patient to have POL.

Most POLs are bilateral and appear homogeneous on imaging.^[6] This feature along with the lack of ascites helpful to distinguish them from epithelial ovarian tumors in presurgical scans.^[6] There is no consensus on the optimal staging schema for POLs. Both the Ann Arbor and the International Federation of Gynaecology and Obstetrics staging approaches have been used. The major prognostic factors reported are stage at presentation, bilateral versus unilateral disease, tumor size, and International Prognostic Index score >2 and histological subtype.^[7]

Figure 1: Sheets of atypical lymphoid cells (H and E, ×400)

Figure 2: Atypical cells show positive reaction for CD45 (DAB, ×400)

Figure 3: Atypical cells show positive reaction for CD79a (DAB, ×400)

Figure 4: Atypical cells show positive reaction for CD10 (DAB, ×400)

Figure 5: Atypical cells show positive reaction for TdT (DAB, ×400)

Among POLs, lymphomas of B-cell origin are the most common with Burkitt's lymphoma and diffuse large B-cell lymphoma accounting for the majority.^[4,8-10] Primary lymphoblastic lymphoma of the ovary is uncommon but has been reported in the pediatric and adolescent

age groups.^[11-13] Acute lymphoblastic leukemia which is biologically similar to lymphoblastic lymphoma has also been reported to involve the ovaries at relapse and can mimic epithelial cancers of the ovary.^[14]

This case is being reported for its rarity and to highlight the importance of accurate histopathology in the diagnosis and management of primary ovarian neoplasms. Furthermore, we would like to highlight the possibility of POL in younger patients who present with homogeneous bilateral ovarian masses, without ascites, with normal serum tumor markers and to stress on the requirement for a preoperative biopsy of such ovarian mass lesions. This approach will be effective in preventing unwarranted major surgical resections and thus preserving fertility in such patients; the majority of whom are young and belong to the reproductive age group, as these tumors are exquisitely chemosensitive with good outcomes when treated with chemotherapy alone.
